

Lab 7: Neural Networks for Music Classification

In addition to the concepts in the [MNIST neural network demo \(./mnist_neural.ipynb\)](#), in this lab, you will learn to:

- Load a file from a URL
- Extract simple features from audio samples for machine learning tasks such as speech recognition and classification
- Build a simple neural network for music classification using these features
- Use a callback to store the loss and accuracy history in the training process
- Optimize the learning rate of the neural network

To illustrate the basic concepts, we will look at a relatively simple music classification problem. Given a sample of music, we want to determine which instrument (e.g. trumpet, violin, piano) is playing. This dataset was generously supplied by [Prof. Juan Bello \(http://steinhardt.nyu.edu/faculty/Juan_Pablo_Bello\)](#) at NYU Steinhardt and his former PhD student Eric Humphrey (now at Spotify). They have a complete website dedicated to deep learning methods in music informatics:

<http://marl.smusic.nyu.edu/wordpress/projects/feature-learning-deep-architectures/deep-learning-python-tutorial/> (<http://marl.smusic.nyu.edu/wordpress/projects/feature-learning-deep-architectures/deep-learning-python-tutorial/>)

You can also check out Juan's [course \(http://www.nyu.edu/classes/bello/ACA.html\)](http://www.nyu.edu/classes/bello/ACA.html).

Loading the Keras package

We begin by loading keras and the other packages

```
In [1]: import keras
```

Using TensorFlow backend.

```
In [2]: import numpy as np
import matplotlib
import matplotlib.pyplot as plt
%matplotlib inline
```

Audio Feature Extraction with Librosa

The key to audio classification is to extract the correct features. In addition to keras, we will need the librosa package. The librosa package in python has a rich set of methods extracting the features of audio samples commonly used in machine learning tasks such as speech recognition and sound classification.

Installation instructions and complete documentation for the package are given on the [librosa main page \(https://librosa.github.io/librosa/\)](https://librosa.github.io/librosa/). On most systems, you should be able to simply use:

```
pip install -u librosa
```

For Unix, you may need to load some additional packages:

```
sudo apt-get install build-essential
sudo apt-get install libxext-dev python-qt4 qt4-dev-tools
pip install librosa
```

After you have installed the package, try to import it.

```
In [4]: import librosa
import librosa.display
import librosa.feature
```

In this lab, we will use a set of music samples from the website:

<http://theremin.music.uiowa.edu> (<http://theremin.music.uiowa.edu>)

This website has a great set of samples for audio processing. Look on the web for how to use the `requests.get` and `file.write` commands to load the file at the URL provided into your working directory.

You can play the audio sample by copying the file to your local machine and playing it on any media player. If you listen to it you will hear a soprano saxophone (with vibrato) playing four notes (C, C#, D, Eb).

```
In [30]: fn = "SopSax.Vib.pp.C6Eb6.aiff"
url = "http://theremin.music.uiowa.edu/sound_files/MIS/Woodwinds/sopranosaxophc

# TODO: Load the file from url and save it in a file under the name fn

import requests
response = requests.get(url, stream=True)
with open(fn, 'wb') as f:
    for block in response.iter_content(1024): # Data will be read in chunks/block
        f.write(block)
```

Next, use librosa command `librosa.load` to read the audio file with filename `fn` and get the samples `y` and sample rate `sr`.

```
In [31]: # TODO
y, sr = librosa.load(fn)
```

Extracting features from audio files is an entire subject on its own right. A commonly used set of features are called the Mel Frequency Cepstral Coefficients (MFCCs). These are derived from the so-called mel spectrogram which is something like a regular spectrogram, but the power and frequency are represented in log scale, which more naturally aligns with human perceptual processing. You can run the code below to display the mel spectrogram from the audio sample.

You can easily see the four notes played in the audio track. You also see the 'harmonics' of each notes, which are other tones at integer multiples of the fundamental frequency of each note.

```
In [32]: S = librosa.feature.melspectrogram(y=y, sr=sr, n_mels=128, fmax=8000)
librosa.display.specshow(librosa.logamplitude(S, ref_power=np.max),
                        y_axis='mel', fmax=8000, x_axis='time')
plt.colorbar(format='%+2.0f dB')
plt.title('Mel spectrogram')
plt.tight_layout()
```

Downloading the Data

Using the MFCC features described above, Eric Humphrey and Juan Bellow have created a complete data set that can be used for instrument classification. Essentially, they collected a number of data files from the website above. For each audio file, they segmented the track into notes and then extracted 120 MFCCs for each note. The goal is to recognize the instrument from the 120 MFCCs. The process of feature extraction is quite involved. So, we will just use their processed data provided at:

<https://github.com/marl/dl4mir-tutorial/blob/master/README.md> (<https://github.com/marl/dl4mir-tutorial/blob/master/README.md>)

Note the password. Load the four files into some directory, say `instrument_dataset`. Then, load them with the commands.

```
In [34]: data_dir = 'instrument_dataset/'
Xtr = np.load(data_dir+'uiowa_train_data.npy')
ytr = np.load(data_dir+'uiowa_train_labels.npy')
Xts = np.load(data_dir+'uiowa_test_data.npy')
yts = np.load(data_dir+'uiowa_test_labels.npy')
```

Looking at the data files:

- What is the number of training and test samples?
- What is the number of features for each sample?
- How many classes (i.e. instruments) are there per class.

```
In [63]: # TODO

# Number of training and test samples
ntr = Xtr.shape[0]
nts = Xts.shape[0]
# len(ytr) == ntr and len(yts) == nts
print('ntr = ', ntr, 'nts = ', nts )

# Number of features for each sample
nfeat = Xtr.shape[1]
#Xtr.shape[1] == 120 and Xts.shape[1] == 120
print('number of MFCC features = ', nfeat)

# How many classes (i.e. instruments) are there per class
types_instr = np.unique(yts)
ninstr = len(types_instr)
print('types_instr ', types_instr, 'therefore number of instruments = ', ninstr)
```

```
ntr = 66247 nts = 14904
number of MFCC features = 120
types_instr [0 1 2 3 4 5 6 7 8 9] therefore number of instruments = 10
```

Before continuing, you must scale the training and test data, `Xtr` and `Xts`. Compute the mean and std deviation of each feature in `Xtr` and create a new training data set, `Xtr_scale`, by subtracting the mean and dividing by the std deviation. Also compute a scaled test data set, `Xts_scale` using the mean and std deviation learned from the test data set.

```
In [61]: # TODO Scale the training and test matrices
import sklearn
Xtr_scale = sklearn.preprocessing.scale(Xtr)
Xts_scale = sklearn.preprocessing.scale(Xts)
```

Building a Neural Network Classifier

Following the example in [MNIST neural network demo \(./mnist_neural.ipynb\)](#), clear the keras session. Then, create a neural network model with:

- nh=256 hidden units
- sigmoid activation
- select the input and output shape correctly
- print the model summary

```
In [150]: from keras.models import Model, Sequential
from keras.layers import Dense, Activation
```

```
In [151]: # TODO clear session
import keras.backend as K
K.clear_session()
```

```
In [152]: # TODO: construct the model
nin = nfeat      # dimension of input data
nh = 256         # number of hidden units
nout = ninstr    # number of outputs = 10 since there are 10 classes

model = Sequential()
model.add(Dense(nh, input_shape=(nin,), activation='sigmoid', name='hidden'))
model.add(Dense(nout, activation='softmax', name='output'))
```

```
In [120]: # TODO: Print the model summary
model.summary()
```

Layer (type)	Output Shape	Param #
hidden (Dense)	(None, 256)	30976
output (Dense)	(None, 10)	2570
Total params: 33,546		
Trainable params: 33,546		
Non-trainable params: 0		

To keep track of the loss history and validation accuracy, we will use a *callback* function as described in [Keras callback documentation \(https://keras.io/callbacks/\)](https://keras.io/callbacks/). A callback is a class that is passed to the fit method. Complete the LoadHistory callback class below to save the loss and validation accuracy.

```
In [153]: class LossHistory(keras.callbacks.Callback):
    def on_train_begin(self, logs={}):
        # TODO: Create two empty lists, self.loss and self.val_acc
        self.loss = []
        self.val_acc = []

    def on_batch_end(self, batch, logs={}):
        # TODO: This is called at the end of each batch.
        # Add the loss in logs.get('loss') to the loss list
        self.loss.append(logs.get('loss'))

    def on_epoch_end(self, epoch, logs):
        # TODO: This is called at the end of each epoch.
        # Add the test accuracy in logs.get('val_acc') to the val_acc list
        self.val_acc.append(logs.get('val_acc'))

# Create an instance of the history callback
history_cb = LossHistory()
```

Create an optimizer and compile the model. Select the appropriate loss function and metrics. For the optimizer, use the Adam optimizer with a learning rate of 0.001

```
In [154]: # TODO
          from keras import optimizers
          lr = 0.001
          opt = optimizers.Adam(lr= lr)#, beta_1=0.9, beta_2=0.999, epsilon=1e-08, decay=
          model.compile(optimizer=opt, loss='sparse_categorical_crossentropy', metrics=
```

Fit the model for 10 epochs using the scaled data for both the training and validation. Use the `validation_data` option to pass the test data. Also, pass the callback class create above. Use a batch size of 100. Your final accuracy should be >99%.

```
In [155]: # TODO
          batch_size = 100
          epochs = 10
          model.fit(Xtr_scale, ytr,
                    epochs=epochs, batch_size=batch_size,
                    verbose=0,
                    callbacks=[history_cb], validation_data=(Xts_scale, yts))
```

```
Out[155]: <keras.callbacks.History at 0x1df5b906cf8>
```

Plot the validation accuracy saved in the `history_cb`. This gives one accuracy value per epoch. You should see that the validation accuracy saturates at a little higher than 99%. After that it "bounces around" due to the noise in the stochastic gradient descent.

```
In [156]: # TODO
iepochs = np.arange(epochs)
plt.plot(iepochs, history_cb.val_acc)
plt.grid()
plt.xlabel('Epoch')
plt.ylabel('Test accuracy')
plt.tight_layout()
plt.show()

# NOTE: ACCURACY IS ABOVE 99% FOR TRAINING ACCURACY BUT NOT FOR TEST ACCURACY (
#ALSO THE MORE YOU TRAIN IT THE BETTER YOUR TRAINING ACCURACY GETS AND THE WORSE
#BECOMES (epoch 30 was 94%)
```

Plot the loss values saved in the history_cb class. Use the semilogy plot. There is one loss value per step. But, plot the x-axis in epochs. Note that the epoch in step i is $\text{epoch} = i * \text{batch_size} / \text{ntr}$ where batch_size is the batch_size and ntr is the total number of training samples.

```
In [157]: # TODO
epoch_index = ieepochs * int(ntr/batch_size)
history_cb.loss = np.array(history_cb.loss)
plt.semilogy(ieepochs, history_cb.loss[epoch_index])
plt.grid()
plt.xlabel('Epoch')
plt.ylabel('Loss')
```

Out[157]: <matplotlib.text.Text at 0x1df5303b198>

Optimizing the Learning Rate

One challenge in training neural networks is the selection of the learning rate. Rerun the above code, trying four learning rates as shown in the vector rates. For each learning rate:

- clear the session
- construct the network
- select the optimizer. Use the Adam optimizer with the appropriate learning rate.
- train the model
- save the accuracy and losses

```

In [138]: # TODO
from keras.models import Model, Sequential
from keras.layers import Dense, Activation
from keras import optimizers

class LossHistory(keras.callbacks.Callback):
    def on_train_begin(self, logs={}):
        # TODO: Create two empty lists, self.loss and self.val_acc
        self.loss = []
        self.val_acc = []

    def on_batch_end(self, batch, logs={}):
        # TODO: This is called at the end of each batch.
        # Add the loss in logs.get('loss') to the loss list
        self.loss.append(logs.get('loss'))

    def on_epoch_end(self, epoch, logs):
        # TODO: This is called at the end of each epoch.
        # Add the test accuracy in logs.get('val_acc') to the val_acc list
        self.val_acc.append(logs.get('val_acc'))

rates = [0.01,0.001,0.0001]
batch_size = 100
nin = 120      # dimension of input data
nh = 256       # number of hidden units
nout = 10      # number of outputs = 10 since there are 10 classes
epochs = 10
iepochs = np.arange(epochs)

loss_hist = {}
val_acc_hist = {}
h_indx = 0

for rate in rates:
    #clear session
    K.clear_session()

    # Create an instance of the history callback
    history_cb = LossHistory()

    #construct the model
    model = Sequential()
    model.add(Dense(nh, input_shape=(nin,), activation='sigmoid', name='hidden'))
    model.add(Dense(nout, activation='softmax', name='output'))

    #construct optimizer
    opt = optimizers.Adam(lr= rate)#, beta_1=0.9, beta_2=0.999, epsilon=1e-08,
    model.compile(optimizer=opt, loss='sparse_categorical_crossentropy', metrics=

    #fit model
    model.fit(Xtr_scale, ytr,
              epochs=epochs, batch_size=batch_size,
              verbose=0, validation_data=(Xts_scale,yts), callbacks=[history_cb])

    loss_hist[h_indx] = history_cb.loss

```

```
val_acc_hist[h_indx] = history_cb.val_acc
h_indx += 1
```

Plot the loss function vs. the epoch number for all three learning rates on one graph. You should see that the lower learning rates are more stable, but converge slower.

```
In [149]: # TODO
epoch_index = iepochs * int(ntr/batch_size)

plt.figure
for k in np.arange(3):
    loss_hist[k] = np.array(loss_hist[k])
    plt.subplot(1,5,2*k+1)
    plt.semilogy(iepochs, loss_hist[k][epoch_index])
    plt.grid()
    plt.xlabel('Epoch')
    plt.ylabel('Loss with learning rate' + np.str(rates[k]))
plt.show()
```
